Executive Summary

Background and Introduction

NSF’s strategic plan clearly acknowledges the growing need for U.S. scientists and engineers to address questions of global scale and significance. It also recognizes that applying the results of basic research to longstanding international challenges—such as epidemics, natural disasters, and the development of alternative energy sources—will require globally engaged investigators working collaboratively with agencies and organizations both within the United States and abroad.

The information included in this Executive Summary and full report resulted from a workshop conducted by Sigma Xi, The Scientific Research Society, on July 28 and 29, 2008, at the U.S. National Science Foundation (NSF) headquarters in Arlington, Virginia. The purpose of the workshop was to gather advice from experts on how to evaluate the impact of international programs that involve U.S. students, researchers, and educators in international scientific and engineering collaborations, such as those funded by NSF’s Office of International Science and Engineering (OISE). The goal of the workshop was to help identify the unique contributions that international collaborations make to promoting excellence in scientific and engineering research and to use that information to develop monitoring and evaluation criteria for OISE programs.

Two specific types of programs were discussed. The first includes programs that focus on funding individual scientists and engineers to begin collaborative projects with international partners for the first time, such as NSF’s International Research Fellowship Program (IRFP), which provides awards to individual postdoctoral scholars for up to two years of international research. The second type of program discussed includes those that involve more complex collaborations across institutions and disciplines, both in the United States and abroad. One example is NSF’s Partnerships for International Research and Education (PIRE), which awards up to $500,000 per year for five years to Ph.D.-granting institutions and involves participants at all stages of their academic careers.

The workshop looked at developing ways to monitor and evaluate such programs in terms of the impact on individuals, institutions, and quality of research—and the extent to which those effects were unique to international collaborations. How do these international collaborations contribute to the creation of globally competent (and therefore globally competitive) scientists and engineers and science and engineering educational and research institutions, and how do they add to the knowledge environment? Effective assessments would be able to compare an international collaboration to a domestic project, measure a project’s contributions to the overall goals of a funding program, evaluate its costs and benefits in terms of human and other resources, and measure the degree to which initial support from NSF led to sustained collaborations even after such funding ended.

Developing Evaluation Approaches to International Collaborative Science and Engineering Activities – Workshop Report

The full report contains discussions and conceptual frameworks for each of the three levels and includes sections on appropriate methods, research agendas, and specific testable hypotheses. This summary provides a brief description of each level and the research questions that arose during the workshop.

**Individual Level**

Anecdotal evidence suggests that students and researchers who participate in international collaborative activities experience a unique set of challenges and opportunities that directly contribute to the knowledge, skills, and behaviors of a globally competent scientist or engineer. In turn, the added knowledge, skills, and behaviors have a direct impact on the career paths of these individuals. Identification of these key elements and their causal relationships is an empirical question.

The following research agendas provide a path for more explicitly assessing the contribution of international collaborations to the global competence of scientists and engineers:

- Examine what other science and engineering programs have done to evaluate the career development of students and faculty who participate in international programs. Support a series of pilot projects that will explore the short- and long-term effects of international experiences on career outputs and outcomes.
- Conduct studies that more fully identify the underlying motives for a scientist’s or an engineer’s desire for international collaboration. Identify possible correlations to previous experiences and level of education and career development. Previous studies can be used as a backdrop for developing motivational variables.
- Support research that seeks to identify the impact of international collaboration on the careers of scientists and engineers at all stages of their career development.
- Identify institutions (both four-year and graduate-degree-granting) and programs to use as models for developing best practices for international experiences. Support the development of systematic monitoring, assessment, and evaluation tools to compare the impact of international experiences across institutions and programs. As part of this project, develop consensus definitions of monitoring and evaluation terms and a common time line. Develop clear distinctions between those involved in the activities and the observers who are doing the monitoring and assessing.
- Support a series of research projects that explicitly link characteristics of global competence (such as curiosity, flexibility, and trust) to professional competence and the development of science and engineering knowledge, skills, and behaviors. Be able to identify experiences (such as putting students in an unfamiliar domestic environment or providing virtual learning opportunities) that might contribute to global competence among scientists and engineers without requiring travel abroad.

**Institutional Level**

In addition to advancing the career development of individual scientists and engineers, another underlying goal of NSF OISE is to enhance the capabilities of the institutions it supports to participate actively and continuously in international collaborations. Of particular importance is the ability of institutions to sustain, deepen, and expand existing international networks to meet new science and engineering challenges and opportunities around the globe. Developing the institutional flexibility to participate in cutting-edge research wherever and whenever it occurs will help to promote globally competent research and educational institutions. Both the funding
Developing Evaluation Approaches to International Collaborative Science and Engineering Activities – Workshop Report

The research areas below are intended to start the process of pinpointing the effects of international collaborations on the knowledge environment and the degree to which international collaborations add to the quality (of outputs and outcomes) of both “normal” science and “transformative research.” Of the three elements that were discussed at the workshop, participants found that this was the most difficult to address.

• Conduct background research to determine what other agencies, institutions, and programs (both within and outside NSF) have done to evaluate their international science and engineering programs in terms of qualitative and quantitative impacts on discovery and innovation. One possibility is to compare the effects that an international component had within NSF disciplinary programs to those without an international component.

• Clearly identify learning styles, methods, techniques, and problem-solving approaches used outside the United States that might help advance science and engineering research. Which of these might facilitate productive research and lead to new discoveries and innovations?

• Develop prototypes of effective international collaborations at all levels of education and research, and include models of both short-term and long-term projects. This process should include a more detailed examination of what it means to produce better research “outputs” and “outcomes.”

• Develop examples of discovery, innovation, and best practices that constitute transformative science, with a focus on those that involved international collaborations. Continue to refine the characteristics of transformative research.

Knowledge Environment Level

Methods

Because of the dearth of quantitative and qualitative studies that directly measure the impact of international collaborations on science and engineering at all three levels, the methods that were
suggested were primarily exploratory in nature. They are intended to define categories (taxonomies) more clearly and to suggest causal links, as well as to produce descriptive and explanatory models. Of particular interest was the development of models that examine the depth and breadth of science and engineering social and information networks that can be established, sustained, and expanded, and the use of both traditional and nontraditional means of communication (CIT) that intercultural science and engineering communications might require.

The discussion centered on the following groups of methods across all three levels:
- Surveys and longitudinal data collection
- Comparative case studies
- Interviews and focus groups
- Social and knowledge (communications) network analysis

**Summary and Conclusions**

Developing effective tools to evaluate such collaborations will take time and money. Participants arrived at the workshop with years of experience participating in, administering and evaluating international projects, but no one was able to offer existing long-term systematic evaluations or models that address all three of the levels of interest to NSF. At this point, most of the evidence remains anecdotal and unsystematic.

To address this shortcoming by doing everything suggested in the report would be quite time-consuming and expensive, and it would require the dedicated efforts of faculty and staff at various institutions for many years. The key recommendation is to develop some short-term feasible metrics that can be used to evaluate the impacts of IRFP and PIRE while studying some of the leading elements to develop more complex models in the future.

It also became clear at the workshop that specific programs such as PIRE and IRFP cannot be studied in a vacuum. Evaluations of their effectiveness must take into account other international activities that are taking place at institutions and the students and faculty involved in them. It was also noted that it is important to study the failures of international collaborations as well as the successes. Another point of agreement is that the impact of international collaborations will vary depending on the subject being studied and the region where the research is being carried out.

The discrepancy between the needs of industry and the needs of U.S. research institutions is another issue that remains unresolved. Industry wants competent U.S. scientists and engineers at all educational levels who are able to work, live, and operate effectively abroad for extended periods of time. Much of the research conducted by industry is applied research. It will result in the development of new products and new markets. Agencies such as NSF, however, want globally competent scientists and engineers to go abroad to conduct cutting-edge basic research and then return to the United States to teach and mentor others and advance U.S. contributions to the global process of research and development. One question that remains is what complementary and integrative roles different agencies and institutions involved in research play in developing global competence. This raises other questions as well, such as whether the process of evaluating international programs will be the same for all participants, including
academic institutions and industry, or whether NSF should develop assessment tools that apply only to agencies with similar goals and strategies.

Next Steps

In order to develop a set of essential, feasible quantitative and qualitative monitoring and assessment tools for NSF OISE programs, the following steps should be taken:

- Determine what NSF and other governmental and nongovernmental agencies here and abroad have done to assess their international science and engineering programs. Identify key elements that can be adapted to NSF program evaluations.
- Prioritize the research agendas identified in this report and the lead NSF offices that might sponsor the research needed in these agendas.
- Develop several request-for-proposals based on these agendas that explore the development of monitoring and assessment tools at the individual, institutional, and scientific-research levels of analysis.
- Work with other agencies to develop a common set of evaluation standards.
I. Introduction

The information included in this report resulted from a workshop conducted by Sigma Xi, The Scientific Research Society, on July 28 and 29, 2008, at the U.S. National Science Foundation (NSF) headquarters in Arlington, Virginia. The purpose of the workshop was to gather advice from experts on how to evaluate the impact of international programs that involve U.S. students, researchers, and educators in international scientific and engineering collaborations, such as those funded by NSF’s Office of International Science and Engineering (OISE). The sixteen invitees responded to a series of questions regarding the development of monitoring and assessment tools that could be used to assess three aspects of collaborative international research: (1) the impact of the collaboration on an individual scientist or engineer; (2) the impact on the institutions involved in the collaboration; and (3) the impact on the quality of science and engineering that resulted from the collaboration. The primary purposes of the workshop were to help identify the unique contributions that international collaborations make to promoting excellence in scientific and engineering research and to use that information to develop monitoring and evaluation criteria for OISE programs. The workshop grew out of a 2006 conference that focused broadly on developing a globally competent U.S. science and engineering workforce.

Two specific types of programs were discussed. The first includes programs that focus on funding individual scientists and engineers to begin collaborative projects with international partners for the first time. These programs are exemplified by NSF’s International Research Fellowship Program (IRFP), which provides awards to individual postdoctoral scholars for up to two years of international research. The goal of the IRFP is to introduce scientists and engineers to collaborative international research early in their careers, thereby facilitating their ability to develop long-term relationships with colleagues abroad and giving them a global perspective on their field.

The second type of program discussed includes those that involve more complex collaborations across institutions and disciplines, both in the United States and abroad. One example is NSF’s Partnerships for International Research and Education (PIRE), which awards up to $2.5 million per year for five years to Ph.D.-granting institutions and involves participants at all stages of their academic careers. PIRE is intended to help institutions in the United States build partnerships with foreign counterparts, with the goals of encouraging cutting-edge research, giving U.S. students international research experiences, and creating new models of international research collaboration.

The workshop focused on developing ways to monitor and evaluate such programs in terms of the impact on individuals, institutions, and quality of research—and the extent to which those

---

3 Biographies of the invitees are included in Appendix I, and the questions that were developed can be found in Appendix II.

4 Information about the 2006 workshop, its subsequent report, and an executive summary can be found on Sigma Xi’s Web site: http://www.sigmaxi.org/global. The report—Embracing Globalization: Meeting the Challenges to U.S. Scientists and Engineers—includes some 90 recommendations to funding agencies and research institutions to help ensure that the U.S. workforce will be able to thrive in a global environment.

5 There are other OISE programs that resemble IRFP and PIRE, but participants were asked to focus on these two. For a complete description of all OISE programs see: http://www.nsf.gov/OISE.
effects were unique to international collaborations. Effective assessments would be able to compare an international collaboration to a domestic project, measure a project’s contributions to the overall goals of a funding program, evaluate its costs and benefits in terms of human and other resources, and measure the degree to which initial support from NSF led to sustained collaborations even after such funding ended.

There are a number of stakeholders—Congressional committees, NSF management, OISE management and program staff, and the Primary Investigators of NSF grants that have an international research or education component—with interests in insuring that NSF funds the most promising proposals. Only long-term monitoring and assessment tools can measure the real impact that international collaborations have on the U.S. science and engineering enterprise. Such evaluations contribute to the internal and external accountability that all government agencies have to these stakeholders and, indeed, to the American taxpayer.

II. Background

Increasing international competition and workforce mobility, combined with a surge in international collaboration in science and engineering research, continue to alter the science and engineering landscape worldwide. To lead within this broader global context, the U.S. science and engineering workforce must build greater capacity for productive international collaborations.

—NSF Strategic Plan

NSF’s strategic plan clearly acknowledges the growing need for U.S. scientists and engineers to address questions of global scale and significance. It also recognizes that applying the results of basic research to longstanding international challenges—such as epidemics, natural disasters, and the development of alternative energy sources—will require globally engaged investigators working collaboratively with agencies and organizations both within the United States and abroad. As recent economic and social trends have indicated, the global economy involves an interconnected web of economic and social networks that impact stakeholders throughout the world. An economic or political crisis in one country has economic, social, and political reverberations around the globe, often with unintended consequences. Now, more than ever, the role that international scientific collaborations and science diplomacy can play to fully meet the challenges and opportunities of advancing discoveries in health, food supply, energy, and environment, and even developing new models of economic development, takes on added significance in the coming decades of the 21st century.

The goal is clear. One problem, however, is that as scientists and engineers use advanced technology to build increasingly complex systems, it becomes more difficult to evaluate their progress toward that goal. Disciplines often have their own evaluative criteria, and these can be hard to compare and contrast to other fields of research. International collaborations add further difficulty by involving different cultures, metrics, and even definitions of “successful.”

The workshop attempted to grapple with these important but complex issues by developing criteria for measuring the effectiveness of international collaborations on three levels:

---

1) The impact on an individual researcher
2) The impact on the institutions involved
3) The impact on the quality of the research produced

The following sections will address each of these three levels.

III. The Individual

Defining Global Competence

As we advance into the 21st century, it is now clear that the rapid pace of science and engineering must be tempered with a new sensibility—an international sensibility that embraces and can bend to accommodate the nuances of cultural diversity.

—Indira Samarasekera

An individual who chooses to participate in international exchanges and collaborations is assumed to return with new attitudes and beliefs that contribute to “global competence.” One definition of global competence is “having an open mind while actively seeking to understand cultural norms and expectations of others, leveraging this gained knowledge to interact, communicate, and work effectively outside one’s own environment.” Gary Downey has applied this definition specifically to engineers, describing a globally competent engineer as one who has “the knowledge, ability, and predisposition to work effectively with people who define problems differently than they do.”

One aspect of the discussion at the workshop focused on whether a person really develops intercultural or global competence during a particular international collaboration. One way to approach this question is to look at global competence as a process that begins with an initial experience in a foreign setting and progresses to the ability to participate effectively in environments around the world. Many researchers might take part in the first steps of this process, but it is possible that only a few will have the leadership skills and knowledge to be able to cooperate in a truly global environment.

In general, students who travel abroad are assumed to acquire or strengthen a number of traits, including openness, curiosity, empathy, trust, and the ability to operate in different cultural settings. Measuring these traits is not easy, however, and it is even more difficult to quantify the differences between those students who take part in international collaborations and those who do not. For individuals involved in science and engineering, another important question is how international collaborations will result in the acquisition of knowledge, skills, and behaviors that strengthen their ability to engage in scientific discovery and innovation.

---

Discussion

**Figure I: Attributes of the Global Engineering Professional**

At the outset of the workshop, participants noted that above all else, students and researchers should be technically and professionally competent in their fields of study. As Figure I indicates, global competency involves applying professional and technical competencies to a broader and more complex international environment. Together, these capabilities are what is expected of a scientist or engineer in the 21st century. The degree to which international collaborative experiences enhance or contribute to these attributes is an empirical question.

While there was agreement on the importance of these skills, there was a noticeable distinction between industry representatives and academics regarding the kinds of individuals and behaviors desired. Industry representatives were interested in the development of global collaborations at all levels of higher education—from community college to postgraduate programs—because there are a variety of tasks and job skills at each level. Moreover, industry representatives want employees from the United States to be able to travel, work, and live abroad for extended periods of time. Academic representatives expressed more interest in ensuring that individuals return to the United States to create new opportunities for themselves and others. One way to classify these differences is that industry may view the movement of
U.S. scientists and engineers to other countries as “brain circulation,” whereas others view it as “brain drain.”

During the course of the workshop, the following types of knowledge, skills, and behaviors were discussed. These can be used as a way to compare those scientists and engineers who have had collaborative international experiences with those who have not.

**Knowledge**
- Knowledge of new methods or techniques not available in the U.S.
- Access to information not available elsewhere or not in English-language journals
- Understanding of different languages and cultures
- Understanding of the different economic, social, and political systems that govern laws and regulations relevant to science and engineering, such as intellectual-property laws
- Knowledge of differences in finance, international standards, global product platforms, and marketing

**Skills**
- Use of new information technology, including software, hardware, equipment, and facilities
- Use of nontraditional means to gather, analyze, and communicate research
- Ability to discern cultural differences in laboratory rules and dynamics
- Ability to develop and expand sustainable international science and engineering networks
- Ability to lead and produce “transformative science” in environments other than one’s own

**Behaviors**
- Operate effectively in foreign environments
- Operate comfortably in foreign environments (e.g., eat native food and live without additional accommodations)
- Participate in additional international or global experiences in the United States and abroad
- Access media that report on international happenings (e.g., internationally oriented newspapers, foreign journals, and foreign-policy journals)
- Publish in foreign journals, participate in international conferences, teach or conduct research abroad for extended periods, publish with authors from outside the United States
- Obtain non-U.S. patents or licenses
Figure II summarizes the discussion about impacts on the individual experiencing international collaborations by 1) delineating differences among the types of scientists and engineers participating in international collaborations; 2) identifying differences among the types of collaborations that may affect the outcomes and outputs of the collaboration; and 3) linking the traits that were discussed with possible knowledge, skills, and behaviors that result from the collaborations.

**Individual Differences**

Some variables that might influence the results of the international experience include the age and maturity of that person and the educational and professional level they had attained at the time of the experience. Whether the person was an undergraduate or senior research professor, for example, will influence the person’s motivations or goals for participating. In addition, where the individual previously participated in international teams, or even that person’s country of origin and international travel experiences, can often influence the degree of comfort and success achieved by the international experience. Finally, whether the individual’s home institution actively supported the experience or put up hurdles to clear before he or she could collaborate might also influence the type of international experience that person had and the short- and long-term outcomes.
Collaboration Types
Not all research or educational experiences are alike, and these differences can affect the impacts of the experience on the individual. For example, some are of short duration and include just one international event, while others can take place over several years. In addition, in some experiences the host institution might be minimally involved, providing primarily logistical support for access to information, for example. Other experiences can involve large multidisciplinary, multinational teams that have day-to-day contact with each other and provide mutual support and key contributions. Thus, the depth and breadth of the science or engineering networks established by the teams can also have an impact on the opportunities made available to the individual participant.

The discipline or subject area as well as the region of the world where the experience took place could also influence the outcome. A physics experiment with access to CERN facilities in Europe provides a very different work environment from in-depth biodiversity field studies in varying types of ecosystems. Working in developing countries can introduce unique challenges and prompt the use of creative coping skills more so than working in cultures similar to that of the United States. Similarly, working in highly developed countries with very different cultures and language structures from the United States (such as Japan or China, for example) also produces its own set of unique challenges.

The different types of experiences will influence not only the impacts on the individuals participating in them, but also the institutions supporting them, and the quality of science and engineering outcomes and outputs that result.

Linking Traits with Specific Science and Engineering Knowledge, Skills, and Behaviors
Post-travel surveys of students traveling abroad indicate the development of a series of attitudes and beliefs, including openness and trust in others. The most interesting research challenge is to link the kind of traits associated with travel-abroad experiences to specific science and engineering knowledge, skills, and behaviors. Workshop participants mentioned several times that international collaborations help to develop cooperative and willing “world citizens,” but it is the role of NSF and other institutions to identify the science and engineering contributions catalyzed by such traits.

Methods
Several methods were mentioned that can help begin to measure the impact that international collaborations have on students and researchers. These include:

- Surveys: The Intercultural Development Inventory (IDI) and the Beliefs, Events, and Values Inventory (BEVI) were mentioned as tools to examine changes in certain traits exhibited by those who have international experiences. However, these indices do not directly relate such traits to science and engineering competence. Additional surveys would need to be developed or adapted from other evaluations to link the traits measured with science and engineering knowledge, skills, and behaviors.

For a description of the IDI, see http://www.mdbgroupinc.com/idi_background.htm. For a description of the BEVI, see http://www.forumea.org/research-bevi.htm.
• Longitudinal data collection: The development of methods and tools to track individuals as their careers progress could provide a means to analyze the effect international experiences have on career paths and success. These tools might include automatic data-collection tools that could be used by subjects to report on career changes.
• Interviews: Responses gathered from qualitative interview questions could root out metrics that could be used to measure how international collaborations enhance an individual’s scientific or engineering career.
• Case studies and focus groups: These could help identify differences between types of international projects and between individuals who do and do not take part in international collaborations.
• Studying IRFP and PIRE: These programs provide interesting comparisons and can be used to assess the impact of international experience on individuals, both those who have international experience early in their careers (IRFP), and those who are involved in established networks of collaboration at various stages of their careers (PIRE). Similar metrics can be used to assess the effect of international collaboration as long as type(s) of experiences can be clearly defined.

Issues and Research Agendas

What are the Sample Populations?
More than 200,000 U.S. students study abroad each year, but very few of them specialize in science or engineering. At this point, we do not really know what types of experiences our undergraduate or graduate students in science, technology, engineering, and mathematics (STEM) fields are having. Moreover, we do not know what percentage of educators and researchers who are not students take part in international collaborations. This is true both for scientists and engineers receiving NSF grants and for the science and engineering population as a whole.

It may be useful to conduct “before-and-after” studies of those who take part in international collaborations, but there must also be measurements that compare these individuals with those who do not take part in such collaborations. Otherwise, there is no way of knowing whether international projects make a unique contribution to science and engineering outcomes. One suggestion at the workshop was that virtual international learning experiences that take place within the United States might help develop some of the same knowledge, skills, and behaviors as travel abroad. This possibility raises the question of whether face-to-face collaborations in foreign settings provide a unique set of elements that no other experience can replicate.

Another problem concerns postdoctoral researchers, assistant professors, and others early in their careers. Is taking part in international collaborations a hindrance for them, or does it contribute to long-term career success?

Research Area 1: Support research that seeks to identify the impact of international collaboration on the careers of scientists and engineers at all stages of their career development.

Motivations
There are a number of possible motivations for a student or researcher to pursue international opportunities, including previous international travel, family ties to a specific region, enhancing
Developing Evaluation Approaches to International Collaborative Science and Engineering Activities – Workshop Report

a resume, or working with leading researchers abroad. These motivations might depend in part on an individual’s stage of career development and level of education.

Research Area 2: Conduct studies that more fully identify the motives for international collaboration. Identify possible correlations to previous experiences and level of education and career development. Previous studies can be used as a backdrop for developing motivational variables.

**Time Line**

It is important to conduct longitudinal studies that measure the effects of international collaborations in both the long term and the short term, and the degree to which one international experience led to others. This raises the question of identifying the appropriate length of time to use when measuring the effect of international collaborations on career development (outcomes) as opposed to career productivity (outputs).

Research Area 3: Examine what other programs have done to evaluate the career development of students and faculty who participate in international programs. Support a series of pilot projects that will explore the short- and long-term effects of international experiences on career outputs and outcomes.

Research Area 4: Identify academic institutions (both four-year and graduate-degree-granting) and specific programs to use as models for developing best practices for international experiences. Support the development of systematic monitoring, assessment, and evaluation tools to compare the impact of international experiences across institutions and programs. As part of this project, develop a consensus of terms and a common time line. Develop clear distinctions between those involved in the activities and the observers who are doing the monitoring and assessing.

**Linking Global Competence Traits to Science and Engineering Knowledge, Skills, and Behaviors**

As stated previously, there has been a lot of discussion regarding the meaning of global competence in terms of specific traits and skills, but these discussions have usually not directly addressed how global competence relates to the professional development of scientists and engineers. It is important to examine how international experiences prepare scientists and engineers to operate in a global environment.

Research Area 5: Support a series of research projects that explicitly link global competence traits to professional competence and the development of knowledge, skills, and behaviors. Be able to identify experiences (such as putting students in an unfamiliar domestic environment or providing virtual learning opportunities) that might contribute to global competence among scientists and engineers without requiring travel abroad.

**Testable Hypotheses**

Throughout the workshop, participants were asked to develop specific, testable hypotheses that would be measured either quantitatively or qualitatively and used to examine the unique contributions that international collaborations provide. Hypotheses that might be used to measure the impact of collaborations on the individual level include:
H1: The earlier a student participates in a meaningful international collaborative experience (ICE), the more likely it is that he or she will stay in the field/earn an advanced degree/attain professional and technical competencies.

H2: Students with ICE on their resume are more likely to get hired by industry or pursue an academic career.

H3: Scientists and engineers with ICE are better able to create, expand, and sustain international networks than those without it.

H4: Scientists and engineers with ICE use different information technologies and other tools to collect, analyze, and disseminate information than those without it. These include nontraditional tools.

H5: Scientists and engineers with ICE develop a unique set of knowledge, skills, and behaviors that those without ICE lack.

H6: Students with ICE make different career choices within and outside STEM fields than those with no ICE.

H7: Students with ICE are more productive (produce higher-quality output) during their careers than those without ICE.

H8: Globally competent scientists and engineers are better able to participate in “transformative” science and engineering. (See Section V.)

Individual Career Development

There are many variables that affect an individual’s career, apart from any international research or educational experiences the individual may have. Family circumstances, institutional barriers, the economy, and even international politics can play direct and indirect roles in career choices. Still, as some of the workshop participants noted, international experiences lay the groundwork for the development of individuals who, over time, will develop the cultural sensitivities necessary to operate in a global environment. Locating good models of international engagement, identifying what types of experiences work best, and integrating international experience into programs that result in globally competent scientists and engineers is a daunting challenge, but it is one that NSF and others must undertake to ensure that international programs produce the desired results.

IV. Institutional Development

In addition to advancing the career development of U.S. scientists and engineers, another underlying goal of NSF OISE is to enhance the capabilities of the institutions it supports to participate actively and continuously in meaningful international collaborations. Of particular importance is the ability of institutions to sustain, deepen, and expand existing international networks to meet new science and engineering challenges and opportunities around the globe. Both the funding institutions and the institutions that they fund were discussed in terms of how to develop evaluation criteria for tracking the impact of international collaborations on the institutions.

These goals raise the question of what it means to be a globally competent institution. How can a college, university, or other academic or research institution actively support its faculty, staff, and students in participating in a global science and engineering environment?
Discussion

Some institutions already have active international programs; other institutions are just beginning to develop them. There are several components to a mature global-engagement program. These include receiving outside funding from NSF and other agencies that support international research and education; contributing the institution’s own human, financial, and infrastructure resources to support international programs; and the encouragement of a global culture both on campus and off by the institution’s leadership. At a globally competent institution, international science and engineering experience would be the rule, not the exception. As with individual career development, creating globally competent institutions is a long-term, evolutionary process that will take place over not just years, but decades.

A number of benchmarks can be used to track an institution’s progress toward global competence in terms of impacts on institutional policies and practices, outreach activities, and evaluation activities. These include:

Institutional policies and practices:
- Inclusion of global competence issues within an institution’s vision, mission, and strategic priorities
- Curriculums with a global perspective and international emphasis
- Courses that integrate language skills with technical science and engineering subjects, including a joint language/science and engineering degree
- Mandatory requirements for students to travel as part of the degree-granting process at all levels
- Providing orientation, mentoring, and other activities for students before, during, and after international programs
- Flexibility to deal with the dynamic environments and different standards and values that are involved in dealing with different cultures
- New centers, multidisciplinary studies, and other academic changes that integrate global activities within the institution
- Backfilling for teachers’ positions for those who participate in international projects abroad
- Developing incentives in terms of promotions and tenure that encourage foreign engagement in science and engineering activities

Outreach:
- The ability to develop, sustain, and expand international science and engineering networks and the information technology and other infrastructure needed for such activities
- Cross-institutional programs with foreign counterparts, including shared credit- and degree-granting standards
- Inviting foreign faculty to lecture at the institution
- Outreach to the broader public to explain the impact of international programs on the quality of science and engineering

Monitoring and evaluation:
- Consciously attending to and measuring the impacts of multiplier effects brought about by international science and engineering programs
Consciously attending to and measuring the impacts of international experiences on career choice and development of its science and engineering faculty and alumni

One major issue underlying the process of attaining the goal of global competence is how NSF programs, such as PIRE and IRFP, affect the ability and motivations of institutions to achieve this goal.

![Diagram showing Institutional Level with subcategories: Faculty, Courses/Curriculums, Students, Infrastructure]

Methods

Evaluating the degree to which NSF programs directly impact an institution’s development is a very complex issue, as many institutions already have international programs. This is especially true of those institutions that are at the forefront of scientific and engineering research. Therefore, workshop participants suggested ways that comparisons could be made between those institutions that receive NSF funding and those that do not. These methods include:

- Social and communication network analyses to examine the degree to which science and engineering networks that resulted from NSF funding were sustained, expanded, and deepened
- Comparative case studies across different projects that would examine similarities and differences in impacts depending on the type of research and where it was conducted
• Focus groups of award recipients that would more clearly identify both specific institutional impacts and institutional barriers to the development of global-engagement programs
• Comparisons across institutions to see which characteristics of a globally engaged institution were enhanced or changed due to specific projects

Issues and Research Agendas
There are several other issues involved in trying to measure the impact of specific NSF programs on the institutions being funded. One such issue is determining the level of the institution to evaluate. Should it be at the level of the entire university or college, or should it be a narrower focus, such as at the school, department, or center level?¹¹

Research Area 1: What is the appropriate level of an institution to study in order to measure the impact of a specific program on that institution? When an institution has multiple international projects simultaneously, how can the direct effects of a PIRE or IRFP grant be separated from other factors?

Another question raised regarding institutional change was NSF’s motivations in funding specific projects. Will NSF fund the best research within a global environment, or will it act as a catalyst for new institutions to initiate international research projects? Understanding the answer to this question is important for assessing what and how much institutional development occurred.

Research Area 2: Conduct studies of funded projects that examine the effect of the type and the duration of the project on any changes in institutional development at the U.S. institution.

One final problem is that whereas some organizations track international exchanges, there is no group that specifically examines the institutional changes that take place when institutions are involved in international science and engineering projects.

Research Area 3: Conduct research to determine if the region of the world where the research is conducted and field of study affect the kinds of institutional changes that take place at the host U.S. institution. As discussed on page 13, an individual may be influenced by the region of the world and the subject area where research is being discussed. US institutions may also have to make different kinds of arrangements depending upon whether the partnering institution is located in a developing country with currency, visa, and other restrictions or a developed one with strong financial and social support systems. Similarly, institutions will also be influenced on the degree of investment needed depending on the field of study. Institutional arrangements with CERN, for example, would be very different in terms of infrastructure support compared to doing biodiversity field research is Botswana.

¹¹ Some surveying has been done of the impact of international experiences on students at the institutional level. See, for example, Green, M. F., et al., Mapping Internationalization on U.S. Campuses: 2008 edition (Washington, DC: American Council on Education), http://www.acenet.edu/programs/international/mapping2008.
Testable Hypotheses

Any testable hypothesis here assumes the ability to place institutions along a spectrum of international engagement, from those that have no or minimal international involvement to those with extensive international programs. These hypotheses can be used to assess the impact of specific programs, such as IRFP and PIRE, on a given institution. Generally, institutions with extensive international experience:

H1: are better able to develop, sustain, and expand international research and education networks to meet research and education challenges.
H2: have developed more flexible infrastructures to adapt to changing arenas for cutting-edge and high-risk areas of research.
H3: have developed new and nontraditional means to communicate data and research findings of international projects.
H4: are more likely to develop multidisciplinary, multicultural research settings with a global emphasis on their campuses.
H5: are more likely to develop curriculums with an international component and to stress learning foreign cultures and languages.
H6: will have a higher retention rate in STEM fields.
H7: will have a higher percentage of students seeking further education in STEM fields.
H8: will have a higher job-placement rate for their students.

V. Improved Science and Engineering Knowledge Environments

Discussion

Participants in the workshop agreed that assessing the impact of international engagement on the quality of science and engineering research is a very difficult task. There seems to be an underlying assumption that international collaborations such as IRFP and PIRE provide unique enhancements to conducting research and creating educational environments that domestic experiences do not provide. It is also assumed that people seek out these experiences for the unique opportunities they offer in terms of access to new equipment, facilities, expertise, data, and phenomena. Finally, there is an assumption that international collaborations provide opportunities to participate in transformative research, whenever and wherever it may occur. Participants expressed the view that many issues in science and engineering are inherently global issues and cannot be successfully addressed without international collaborations. A globally competent science and engineering community, then, is one that avails itself of opportunities for new discoveries, knowledge, and innovation regardless of location.

The United States is now just one actor in an ever-expanding global research community. Other nations are increasingly funding high-risk, high-payoff research and creating international research consortia. The question for the United States is how to use the nation’s resources to ensure a high return on investment in international science and engineering collaborations.

For an initial discussion of “transformative” research, see National Science Board, Enhancing Support of Transformative Research at the National Science Foundation (Arlington, VA: National Science Foundation), May 7, 2007.
Answering that question requires the development of a set of metrics that measure the impact of international collaborations on the quality of science and engineering knowledge and education. What new opportunities does working with foreign colleagues offer U.S. scientists and engineers? What methods can be used to track the unique effects of such collaborations? Do they, in fact, lead to “better” science and engineering? One note: It may require a long timeframe to track the contributions of international collaborations to advancing and changing science and engineering in the United States.

Some of the possible benefits of international collaborations that were discussed are:

- New methods for solving problems
- New approaches to learning
- New equipment, tools, and facilities
- Access to experts
- Access to new information
- Access to phenomena (such as a specific geological site, species, ecology, or weather pattern)
- Creation of new “consumers” or “markets” for knowledge
- Understanding of international standards or culturally laden rules for creating and disseminating knowledge
- New intellectual property, such as foreign patents, licenses, publications, citations, and recognition
- A broader societal, political, or economic impact

Aspects relating to “transformative” science that could be explored might include:

- Peer recognition of cutting-edge or innovative science and engineering
- New subfields within a discipline
- New interdisciplinary foci
- New technologies
- Paradigm shifts
- More and/or better publications in peer-reviewed journals
- Awards and grants from diverse sources
Figure IV provides a conceptual framework for visualizing how international research collaborations contribute to both “normal” and “transformative” science. These contributions contain both science “outputs” and “outcomes,” although many of the reports addressing the nation’s loss of its competitive edge focus on outputs, such as patents, publications, citations, and relative research and development expenditures. New metrics are needed to measure the effects of U.S. participation in the global science and engineering environment and how that participation affects the quality of the science and engineering that the nation produces.

**Methods**

Participants suggested several methods for beginning the process of defining and refining aspects of research that are uniquely improved by international collaboration. Preliminary research must be done to develop categories and comparative samples for all types of these collaborations, from single, short-term initial visits to long-term, complex, multidisciplinary, multinational projects. Among the methods suggested are:

- Creation of an initial glossary of evaluation terms so that project evaluators would be operating with the same working definitions
- Interviews with participants in these projects to help answer the question: What in this work could not have happened if it were not international?

---

• Focus groups of participants in similar and dissimilar projects to focus on specific elements of knowledge outcomes and outputs
• Case studies of specific projects that delineate similarities and differences between program designs and evaluation criteria. It is important to note whether the approach used is inductive or deductive.
• Knowledge-network analysis, including the use of new or nontraditional ways of generating, analyzing, and communicating information

**Issues and Research Agendas**

The research areas below are intended to start the process of pinpointing the effects of international collaborations on the knowledge environment. Of the three elements of impact, this was the most difficult to address.

Research Area 1: Determine what other agencies, institutions, and programs (both within and outside NSF) have done to evaluate their international science and engineering programs in terms of qualitative and quantitative impacts on discovery and innovation. One possibility is to compare the effects that an international component had within NSF disciplinary programs to those without an international component.

Research Area 2: Clearly identify learning styles, methods, techniques, and problem-solving approaches used outside the United States that might help advance science and engineering research. Which of these might facilitate productive research and lead to new discoveries and innovations?

Research Area 3: Develop prototypes of effective international collaborations at all levels of education and research, and include models of both short-term and long-term projects. This process should include a more detailed examination of what it means to produce better research “outputs” and “outcomes.”

Advances in information technology, among other factors, have contributed to the acceleration of new discoveries and the development of new fields and new paradigms. Still, it remains a long-term process for “normal science” to become “transformative science.”

Research Area 4: Develop examples of discovery, innovation, and best practices that constitute transformative science, with a focus on those that involved international collaborations. Continue to refine the characteristics of transformative research.

**Testable Hypotheses**

Compared to research collaborations based in the United States alone, international research collaborations will result in:

H1: access to new information, expertise, tools, facilities, and/or phenomena not found in the United States.
H2: development of new methods, technologies, and approaches to problems.
H3: use of nontraditional and new ways to record and analyze data and communicate research findings.
H4: understanding of new standards, designs, and intellectual-property approaches not found in the United States.
H5: obtaining foreign patents, licenses, and other intellectual property.
H6: expanded, flexible, and sustainable science and engineering research networks that can take advantage of new research opportunities wherever they occur.
H7: a greater probability of transformative research.

Summary and Conclusions

Summary
Measuring the impact of international collaborations on science and engineering is not an easy task. Developing effective tools to evaluate such collaborations will take time and money. Participants arrived at the workshop with years of experience participating in, administering, and evaluating international projects, but no one was able to offer existing long-term systematic evaluations or models that address all three of the levels of interest to NSF—the impact on the individual, on the institution, and on the quality of research.

Conclusions
The one-and-a-half-day workshop was composed of participants involved in advancing international engagement within their institutions, either through direct involvement or through evaluating international projects. It is clear that there are few, if any, proven quantitative or qualitative metrics that can be used to assess the effects of international collaborative research programs on individuals, institutions, and research. At this point, most of the evidence remains anecdotal and unsystematic.

To address this shortcoming by doing everything suggested in this report would be quite time-consuming and expensive, and it would require the dedicated efforts of faculty and staff at various institutions for many years. The key recommendation is to develop some feasible short-term metrics that can be used to evaluate the impacts of IRFP and PIRE while studying some of the leading elements to develop more complex models in the future.

It also became clear at the workshop that specific programs such as IRFP and PIRE cannot be studied in a vacuum. Evaluations of their effectiveness must take into account other international activities that are taking place at institutions and the students and faculty involved in them. Participants were involved in administering or evaluating a variety of programs other than IRFP and PIRE, and they brought their own experiences and perspectives to bear on the discussion. It was also noted that it is important to study the failures of international collaborations as well as the successes.

Another point of agreement is that the impact of international collaborations will vary depending on the subject being studied and the region where the research is being carried out. Participants in these projects may also have different motivations—they may be seeking to improve the infrastructure for conducting research, or they may be pushing the frontiers of scientific knowledge.

The differences between the needs of industry and the needs of U.S. research institutions is another issue that remains unresolved. Industry wants competent U.S. scientists and engineers at all educational levels who are able to work, live, and operate effectively abroad for extended
periods of time. Much of the research conducted by industry is applied research. It will result in the development of new products and new markets. Agencies such as NSF, however, want globally competent scientists and engineers to go abroad to conduct cutting-edge basic research and then return to the United States to teach and mentor others and advance U.S. contributions to the global process of research and development. One question that remains is what complementary and integrative roles different agencies and institutions involved in research play in developing global competence. This raises other questions as well, such as whether the process of evaluating international programs will be the same for all participants, including both academic institutions and industry, or whether NSF should develop assessment tools that apply only to agencies with similar goals and strategies.

At the end of the workshop, each participant was asked to make some closing remarks. Here are some of the more noteworthy conclusions:

- There are many research questions and some basic metrics, but more needs to be done in terms of evaluations and basic research on the topic.
- In developing evaluation criteria, it is important to understand who the audience is. What information is needed, and to whom should it be provided? Would qualitative or quantitative information be more effective for a particular audience?
- Evaluation does not have to begin and end with numbers. Numbers can be supported by qualitative knowledge and experience. Do not apply different methodologies for different audiences.
- Strategically integrate quantitative and qualitative indicators.
- There is a need to find key indicators of success.
- Multiplier effects should be used to obtain the biggest bang for the buck.
- International collaborations accomplish more than simply contributing to building global competence.
- There is an enormous landscape of indicators. What is the purpose of evaluation: building capacity? Facilitating good programs? Predicting success?
- It is important to select a small but important group of factors when conducting evaluations. The principle of good assessment is to measure just enough. Contact primary investigators and ask them what questions need to be asked to evaluate international collaborations. What is the minimum set to get at the richness?
- Primary investigators need to be well prepared to evaluate programs—give them assessment tools.
- Develop a catalog of data collected by those involved in collaborations. Collate all these resources to find out who is doing what.
- There is a need to identify not only what worked, but what did not work.
- There is a need to link personal with professional growth and to continue to test hypotheses over time.
- Develop the idea of a logic model or theory of change.
- The levels of interest are overlapping and can be hard to delineate.
- We’re not done yet—a majority of the work remains to be done.

**Next Steps**

Evaluating programs such as IRFP and PIRE should not be done without background research into existing evaluation methods and tools used by programs such as Engineers Without
Borders, programs run by the Gates Foundation in the developing world, and United Nations programs that provide education and research experiences in remote parts of the world.

1. Find out which of the other programs at NSF have conducted evaluations of their programs—especially those programs that address the quality of scientific research—and whether those metrics can be applied to IRFP and PIRE.

2. Through meetings, interviews, and/or workshops, examine what other U.S. government agencies and granting institutions (such as NIH, the Departments of Energy, Agriculture, and Education, NASA, USAID, the Gates Foundation, and the Ford Foundation) have done to evaluate their international programs relative to domestic ones.

3. Through meetings, interviews, and/or workshops study what other non-U.S. government agencies and other institutions (such as the European Union, NATO, and the International Council for Science) have done to evaluate their international programs.

4. Prioritize the research agendas identified in this report and the lead NSF offices that might sponsor the research needed in these agendas.

5. Develop several request-for-proposals based on these agendas that explore the development of monitoring and assessment tools at the individual, institutional, and scientific-research levels of analysis.

The goal of the National Science Foundation is to advance excellence in scientific and engineering research. To fulfill that mission, it is essential to develop key monitoring and assessment tools for all NSF programs, especially those that promote global competence. Other nations have taken purposeful steps to train their scientists and engineers to succeed in an international environment. We can learn from these efforts even as we continue to develop our own understanding of how best to advance scientific and engineering research as it becomes an increasingly diverse and global enterprise.
Appendix I
PARTICIPANT CONTACT INFORMATION AND BIOGRAPHIES

1. **Bhandari, Rajika**  
   Director of Research and Evaluation  
   Institute of International Education  
   809 United Nations Plaza  
   New York, NY 10017-3580  
   Tel: 212-984-5347   rbhandari@iie.org  
   www.iie.org

   Rajika Bhandari directs IIE’s research and program evaluation activities and leads two major research projects—*Open Doors* and *Project Atlas*—that measure international higher education mobility at the domestic (U.S.) and international level. She also conducts evaluations of IIE’s international scholarship and fellowship programs. Before joining IIE, Bhandari was a Senior Researcher at MPR Associates, an educational research firm in Berkeley, California, that provides research and evaluation services to the U.S. Department of Education, state departments of education, and foundations. She also served as the Assistant Director for Evaluation at the Mathematics and Science Education Network at the University of North Carolina at Chapel Hill, where she directed research and evaluations of mathematics and science education pre-college and professional development programs. Bhandari has substantial experience conducting educational research in the U.S. and in India on topics such as women and education in developing countries, immigrant parents’ participation in children’s education in the U.S., and adult education and lifelong learning. She holds a doctoral degree in psychology from North Carolina State University and a B.A. (Honors) in psychology from the University of Delhi, India.

2. **Chang, Yating**  
   Assistant Director, Global Engineering Programs  
   Purdue University  
   Civil Engineering Building Rm#G175, 550 Stadium Mall Drive  
   West Lafayette, IN 47907, USA  
   Tel: 765-496-1810   ychang@ecn.purdue.edu

   Yating Chang’s role as assistant director involves raising the participation and impact of global experiences undertaken by students in Purdue’s College of Engineering. Chang has an M.S. in cross-cultural psychology and an Ed. D degree in higher education administration from the Peabody College at Vanderbilt University in April 2007.

   As the Study Abroad Coordinator at Western Kentucky University from 2001–2006, she drove a threefold increase in global educational experiences, working with a predominately local/in-state student population that does not have a natural inclination for study abroad (many being the first in their family to attend college). This work experience—the engagement of underrepresented populations in education abroad—has become her focus. At her current position, Chang works to promote global education to engineering majors—another underrepresented population in study abroad programs. During her career at Purdue University, the number of engineering majors participating in overseas study has increased from 86 to 224. Her main responsibilities include engagement of both students and faculty members at Purdue University to embrace global engineering mindsets and practice. She has served as the program chair for the NSF Grantee Conference of International Research and Engineering Education (IREE) from 2007–2008.

   Chang is a committee member of the Sub-Committee of Underrepresentation in Education Abroad in Education Abroad of NAFSA: Association of International Educators. Concurrently, she serves as the 2008 network leader of the International Education Leadership Development network of NAFSA. She has
organized conference and workshop sessions on media relations for international educators, ethics in study abroad programs, and on the different approaches required when advising Chinese-origin students from different countries. She served on the Board of Trustees (2002–2006) of the Cooperative Center for Study Abroad, as Fulbright Advisor, and as a Selection Panelist for the Gilman International Scholarship Program.

Chang was born in Taiwan, grew up in Singapore, and has traveled to 26 different countries.

3. **Frehill, Lisa**  
Executive Director  
Commission on Professionals in Science and Technology  
1200 New York Ave., NW, Suite 113  
Washington, DC 20005  
Tel: 202-326-7080  
lfrehill@cpst.org  
www.cpst.org

Lisa Frehill holds a doctoral degree in sociology with a minor in systems engineering from the University of Arizona and a bachelor's degree in industrial engineering from General Motors Institute (now Kettering University). Prior to coming to CPST, Dr. Frehill was an Associate Professor of sociology at New Mexico State University (NMSU). She was also the Program Director and Principal Investigator of that institution's National Science Foundation–funded ADVANCE: Institutional Transformation award and served for a year at the University of California at Irvine as the ADVANCE Program Director.

4. **Gerhardt, Lester**  
Vice Provost and Dean of Education  
Rensselaer Polytechnic Institute  
110 Eighth Street  
Troy, NY 12180  
Tel: 518-276-6400  
gerhal@rpi.edu

Lester Gerhardt’s career combines industrial and academic experience. At Rensselaer Polytechnic Institute, his specialty is digital signal processing, emphasizing image processing, speech processing, and brain computer interfacing, and he conducts sponsored research and teaches in this field. He has been actively involved in academic administration concurrent with his professorial career. He has served in the roles of Chair of the Department of Electrical, Computer, and Systems Engineering, which was then cited as the most improved department in the U.S. at the time by the National Academy of Engineering; Founding Director of the Center for Manufacturing Productivity, which was then the second such Center in the U.S.; Director of the Computer Integrated Manufacturing Program, which then won the National LEAD (Leadership, Excellence, and Development) Award; Associate Dean of Engineering for Research; a Vice President of Research Administration and Finance and was the Inaugural Recipient of the National ASEE Research Administration Award; Dean of Engineering; and most recently as Vice Provost and Dean of Graduate Education.

Gerhardt has served as a delegate to NATO and as a consultant to the governments of Singapore, Portugal, Canada, Germany, and the United Kingdom. He co-founded the ongoing Global Engineering Education Exchange Program in 1995; originated the Rensselaer Education Across Cultural Horizons (REACH) Program requiring an international experience of each undergraduate student in 2008; served on the International Advisory Board of the ASEE; was awarded an honorary doctorate by the Technical University of Denmark; has numerous presentations and publications on the subject of globalization of higher education; and travels globally extensively.

He is an active consultant to industry, government, and academe, sits on the board of a privately held company, is a Fellow of the IEEE and ASEE; and holds several patents.
5. **Harris, Roger**  
Sigma Xi, The Scientific Research Society  
3106 East NC Highway 54, P.O. Box 13975  
Research Triangle Park, NC 27709  
Tel: 800-243-6534    rharris@sigmaxi.org  
www.sigmaxi.org

Roger Harris is Director of Emerging Technologies and Research Analysis at Sigma Xi, The Scientific Research Society.

In this role, he strategizes, guides, and implements key business plan features of the 60,000-member global scientific society. Among his other responsibilities, Roger created and implemented a strategic communications and marketing plan. He supervises a suite of member communications vehicles including print media and direct and electronic mail. His most recent initiative is to bring Web 2.0 functionality to the organization by introducing collaborative, interactive online media such as blogs, wikis and forums, and a full-featured social networking platform. He is also a former *American Scientist* contributing editor.

Harris has extensive international experience, including being raised in Africa, and he has traveled to 47 countries in Africa, Europe, and South America. He is the creator and proprietor of an educational Web site about the Amazon, http://www.junglephotos.com, and coauthor with Peter Hutchison of *The Amazon: The Bradt Travel Guide*, the third edition of which was published in August 2007.

6. **Herman, Joan**  
Director, National Center for Research on Evaluation, Standards, and Student Testing  
CRESST/UCLA  
300 Charles E. Young Drive North  
Los Angeles, CA 90095-1522  
Tel: 310-206-3701    herman@cse.ucla.edu  
http://www.cse.ucla.edu/about.html

Joan Herman is Director of the National Center for Research on Evaluation, Standards, and Student Testing (CRESST) at UCLA. Her research has explored the effects of accountability and assessment on schools and teaching and the design of assessment systems to support school planning and instructional decision-making. Her recent work has focused on the validity and consequences of teachers’ formative assessment practices and the design of new indicators for measuring program implementation and impact.

Herman has strong interests in bridging research and practice, particularly in applications serving English Language Learners and at-risk students. She is a frequent advisor in prominent state and federal research and development enterprises, including repeated service to the National Academy, and has been active in a variety of international collaboratives. She is past president of the California Educational Research Association; has held a variety of leadership positions for the American Educational Research Association, including current service as a member-at-large and liaison to international initiatives; serves on the executive board of Knowledge Alliance; and is current editor of *Educational Assessment*. 
7. **Kirk, Elizabeth**
   Visiting Scholar
   Sigma Xi, The Scientific Research Society
   3106 East NC Highway 54, P.O. Box 13975
   Research Triangle Park, NC 27709
   Tel: 302-645-9061    ejkirk@verizon.net

Elizabeth Kirk is a consultant on issues relating to international science, technology, security, and science policy. She is currently a Visiting Scholar at Sigma Xi, The Scientific Research Society, in Research Triangle Park, NC, working on an NSF grant focusing on the development of a globally engaged U.S. scientific, technical, and engineering workforce. Prior to that, she organized Capitol Hill and other briefings on science and security for Women in International Security (WIIS) under a John D. and Catherine T. MacArthur Foundation program.

From 2002–2003, Kirk served as the Technical Liaison for the President’s Information Technology Advisory Committee (PITAC) at the National Coordination Office for Information Technology Research and Development. From 1988–2002 she was Senior Political Scientist and Program Director in the International Directorate of the American Association for the Advancement of Science. Prior to that, she was a Systems Analyst at the Mitre Corporation’s Battlefield Systems Division. Kirk received her B.A. from Douglass College, Rutgers University, and her M.A. and Ph.D. from Purdue University.

8. **Kuber, Andre**
   Hewlett Packard
   Tel: 650-857-5989    andre.kuber@hp.com

Andre Kuber works extensively with a wide variety of universities and business schools, including UCLA, University of Florida in Gainesville, Stanford University, Dartmouth and UCLA-Berkeley’s Haas Business School, in collaboration on supply chain management and operations research, focusing on mutual benefits to both academia and the businesses involved. One of the challenges he addresses in this collaboration is that the needs of academia and business are difficult to align, but they depend on one another to be successful.

He is also a leader in the application of Web 2.0 technologies to training, and in measuring the impact of training on business results. Kuber has a master’s degrees in both instructional design and applied physics. He is fluent in English, Dutch, French, and German.

9. **Kupfer, Linda**
   National Institutes of Health
   Bethesda, MD
   Tel: 301-496-3288    kupfer@mail.nih.gov

Linda Kupfer is currently the Deputy Director of the Division of International Science Policy, Planning, and Evaluation at the Fogarty International Center (FIC), NIH. She directs strategic planning and evaluation at Fogarty. From 2005–2006, Kupfer was the Acting Director of the Office of Evaluation for the entire NIH.

Kupfer obtained her B.A. from Cornell University and her Ph.D. in pharmacology from Columbia University. She was an AAAS Diplomacy Fellow at the State Department in 1984 and remained at the State Department in Oceans and Environmental Sciences until 1987, traveling to China and Southeast Asia to negotiate science agreements. She spent 13 years at NOAA (National Oceanic and Atmospheric Administration), initially working in the agency’s International Activities office and finally as program director of the marine biotechnology extramural program in the national office of the National Sea Grant College Program. While in Sea Grant, Linda and her colleagues...
developed a Framework for Scientific Program Evaluation. The evaluation procedure, which included the development of criteria and benchmarks, was implemented for all Sea Grant Programs. A similar framework has been implemented at Fogarty for six years.

10. **Matherly, Cheryl**  
   Associate Dean for Global Education  
   University of Tulsa  
   3126 East 5th Place  
   Tulsa, OK 74104  
   Tel: 918-631-3229  
   cheryl-matherly@utulsa.edu

Cheryl Matherly is Associate Dean for Global Education and Applied Assistant Professor of Education at the University of Tulsa, where she directs the institution’s international study, work, and volunteer programs. She is currently directing the university’s strategic initiatives with universities in China. Matherly’s special area of interest is the impact of globalization on the workplace. She currently co-directs the INNOVATE conference, which involves students from five countries in the study of globalization and technology in Asia, and the NanoJapan program, which is funded by the National Science Foundation in order to expand international research opportunities for science and engineering majors. NanoJapan was recognized by the Institute of International Education in 2008 with the prestigious Andrew Heiskell Award for Innovation in International Education in the category of study abroad. Matherly has written numerous articles for national publications on international work opportunities. She is the recipient of two Fulbright grants for international education administrators (Germany and Japan).

11. **Matthews, Martha**  
   Manager, Global Quality Training  
   Biogen Idec  
   5000 Davis Drive  
   Research Triangle Park, NC 27709  
   Tel: 919-993-1216  
   Martha.Matthews@biogenidec.com

Biogen Idec is a global research, development, manufacturer, and distributor of biotech therapeutic products for autoimmune diseases and certain types of cancer encompassing 4,000 employees and $2 billion in annual sales.

Matthews is an accomplished executive with extensive experience leading outstanding training and development opportunities within biotechnology, pharmaceutical, and environmental management organizations. She is an expert within employee training / instruction, performance improvement systems, instructional design, team development, and policy development / implementation in lean Six Sigma environments. She has demonstrated talent in sales territory growth, marketing, regulatory compliance, and biotech research and development. An articulate communicator, with exceptional interpersonal skills, she has effectively led and mobilized individuals and work teams to accomplish objectives and maximize impact. To date educational programs and process improvements have resulted in substantial cost and efficiency savings for Biogen Idec.

Matthews is a member of the North Carolina Workforce Development Commission and on the Advisory Board of the Biomanufacturing Training and Education Center. She received her B.A. from Emmanuel College, a Master of Public Health from Boston University, Six Sigma Black Belt Certification from the University of Texas, Austin, and is pursuing a Doctorate in adult education from North Carolina State University.
12. **Novotny, Eric**  
Senior Vice President  
Civilian Research and Development Foundation  
1530 Wilson Boulevard 3rd Floor  
Arlington, VA 22209  
Tel: 703-600-3441    enovotny@crdf.org  
www.crdf.org

Eric J. Novotny manages CRDF’s five operating divisions and coordinates all program planning and execution. He brings to CRDF more than 20 years of combined experience in international high technology business partnerships, program development, and administration. Previously, Novotny was Vice President, Marketing, at Lockheed Martin Corporation, where he directed the company’s ventures to channel Russian defense and space technologies into international markets for peaceful purposes. He has also served as a consultant to numerous government agencies and corporations on forging international partnerships, negotiating technology-transfer agreements, and developing successful funding strategies. He was also Vice President, Europe, for Hughes Electronics, based in Brussels, Belgium. Novotny is presently an Adjunct Professor at American University’s School of International Service. He is a graduate of Georgetown University, where he received his Ph.D. in international relations, and of Templeton College, Oxford.

13. **Olds, Barbara**  
Associate Vice President of Educational Innovation  
Colorado School of Mines  
Golden, CO 80401  
Tel: 303-384-2410    bolds@mines.edu

Barbara M. Olds is Associate Provost for Educational Innovation and Professor of Liberal Arts and International Studies at the Colorado School of Mines (CSM) where she has been on the faculty since 1984. She received her B.A. from Stanford University and her M.A. and Ph.D. from the University of Denver, all in English. From 2003–2006 she was on leave at the National Science Foundation, where she served as the Division Director for the Division of Research, Evaluation, and Communication (REC) in the Education and Human Resources Directorate. During the 2006–2007 academic year, Barbara was a part-time visiting professor in Purdue University’s Engineering Education Department. Her research interests focus primarily on understanding and assessing engineering-student learning, including recent work developing concept inventories for engineering topics with colleagues from CSM and Purdue. She has participated in a number of curriculum innovation projects and has been active in the engineering education and assessment communities. Olds is a Fellow of the American Society for Engineering Education (ASEE), currently serving as the Chair of the International Advisory Committee of ASEE. She is also a member of the Advisory Committee for NSF’s Office of International Science and Engineering, and was a Fulbright lecturer/researcher in Sweden.

14. **Peters, Michael**  
Professor of Education  
Department of Education Policy Studies  
University of Illinois at Urbana-Champaign  
Tel: 217-244-0753    mpet001@uiuc.edu

Michael A. Peters is professor of education in the Department of Educational Policy Studies at the University of Illinois at Urbana-Champaign, where he was invited to join the faculty on the basis of an excellence hire program in 2005. He also currently holds an adjunct appointment at the Royal Melbourne Institute of Technology in Australia. He previously held a joint professorial appointment at the University of Glasgow, United Kingdom, and the University of Auckland, New Zealand. He was
appointed to a personal chair in Education at Auckland in 2000 and also held the position of Research Professor at the University of Glasgow with the brief to provide research leadership and help to build a research culture in the new Faculty of Education.

He also has acted as a consultant to various world governments on education policy and the knowledge economy as well as an advisor to national and international research organizations and funding agencies.

His interests focus broadly on education, philosophy, and public policy and he has written many books and academic papers, including: Global Knowledge Cultures (Sense, 2008) with Cushla Kapitzke; Knowledge Economy, Development and the Future of Higher Education (Sense, 2007); Building Knowledge Cultures: Education and Development in the Age of Knowledge Capitalism (Rowman & Littlefield, 2006), with Tina Besley. Currently, he is writing a number of books, including: Degrees of Freedom: Openness of Science and Education in the 21st Century (Trans. Portuguese, Edições Pedago); The Virtues of Openness (Paradigm), both with Peter Roberts; and a trilogy: Creativity and the Global Knowledge Economy; Global Creation: Space, Mobility and Synchrony in the Age of the Knowledge Economy; and Imagination: Three Models of Imagination in the Age of the Knowledge Economy (Peter Lang) with Simon Marginson and Peter Murphy.

15. Stallman, Elizabeth
Research Assistant, SAGE Grant Project
University of Minnesota
330 Wullung Hall
Minneapolis, MN 55455
Tel: 612-624-7435 stall004@umn.edu
http://www.education.umn.edu/projects/sage/

Elizabeth Stallman is a Ph.D. candidate in the comparative and international development education program at the University of Minnesota. She is also the lead research assistant on a three-year grant project titled, "Beyond immediate impact: Study abroad for global engagement." Her research interests include racial and ethnic identity, intercultural sensitivity, education abroad, college student development, and internationalization of the campus.

Stallman received her M.A. in international educational development in 2001 from Teachers College, Columbia University, where she also served as assistant director of International Services. She received her B.A. in international politics from Penn State University. From 1994 to 1996 she was a JET Program participant for which she taught English to Japanese high school students in Shizuoka, Japan. Her earliest connection to international science collaborations was with her first job at the American Association for the Advancement of Science.

16. Stashko, Ed
Vice President for Global Programs and Partnerships, Organization for Tropical Studies
Duke University
Box 90630
Durham, NC 27708
Tel: 919-684-5774 estashko@duke.edu
www.ots.duke.edu

Ed Stashko oversees the international education and research programs of OTS in South America, Mexico, and South Africa. OTS created the Global Programs and Partnerships Division (GPP) to scale up the availability of OTS-level education and training opportunities in science, management, conservation, and policy across the tropics. GPP is concentrating on building partnerships that strengthen the capacity of tropical country institutions to create and support their own programs, that create synergies with other international organizations with complementary knowledge, skills, and resources, and that engage the
expertise within the OTS consortium of more than 60 institutions. Stashko has his Ph.D. in ecology and evolution from Northwestern University and has worked in international field-based education and training in Costa Rica, Mexico, Turks and Caicos, Canada, Palau, Australia, Kenya, South Africa, and South America. He also provides expertise in program assessment and evaluation, training and educational methodology, and health and safety for field programs.

17. **Strachan, William R.**  
Program Director, Technical Recruiting  
IBM TJ Watson Research Center  
P.O. Box 218  
Yorktown, NY 10598/MS 06-040  
Tel: 914-945-2890    strachen@us.ibm.com  

William R. Strachan has been with IBM for 32 years. He has held multiple management and middle management positions within IBM’s Research Division. His background is in device technology, overseeing the clean room operations for both advance silicon technology and high resolution LCD displays. Currently, Strachan is the Technical Recruiting Program Director for IBM’s Research Division and is responsible for both Ph.D. university recruiting as well as diversity outreach initiatives.

18. **Vaz, Richard F.**  
Dean, Interdisciplinary and Global Studies  
Worcester Polytechnic Institute  
100 Institute Road  
Worcester, MA 01609 USA  
Tel: 508-831-5344    vaz@wpi.edu  

Richard F. Vaz received the Ph.D. in electrical engineering from Worcester Polytechnic Institute (WPI), focusing on signal analysis and machine vision. He held systems and design engineering positions with the Raytheon Company, GenRad Inc., and the MITRE Corporation before joining the WPI Electrical and Computer Engineering faculty in 1987.

Vaz is currently Dean of Interdisciplinary and Global Studies at WPI, with oversight of WPI’s nationally-recognized Global Perspective Program, through which more than 500 students per year complete research projects at one of 24 Project Centers located in Africa, Asia, Australia, Europe, and the Americas. He also leads an academic unit focusing on teaching and research in regional and local sustainability. His interests include experiential learning, engineering design and appropriate technology, and internationalizing engineering education. He has developed and directed interdisciplinary and technical student research projects in Australia, England, Ireland, Italy, Morocco, Namibia, the Netherlands, Thailand, and the U.S.

Vaz is a member of IEEE, ASEE, Sigma Xi, and Eta Kappa Nu, and since 2004 has served as a Senior Science Fellow of the Association of American Colleges and Universities. He has published and presented widely and is the recipient of numerous teaching and advising awards, including the WPI Trustees’ Awards for Outstanding Teaching and for Outstanding Advising.
Appendix II

DISCUSSION QUESTIONS

#1 Breakout Sessions: Evaluation at the Individual Level

Section I: Global Competence – Knowledge Skills, Intangibles, and Career Development

A globally competent engineer has been defined as one who has “the knowledge, ability, and predisposition to work effectively with others who define problems differently.”

What kind of **skill sets**, tangible and intangible, do students and researchers acquire from international scientific and engineering collaborations?

Please identify several tangible competencies that relate to knowledge, skills that result from having access to expertise, phenomena, data, and/or facilities and equipment in international settings.

Please identify some intangible skills (such as “flexibility”) that one may acquire by conducting collaborative research abroad.

Which of these competencies can be gained by those who do not travel? What competencies—virtual or otherwise—might be useful?

How could we measure the impact of international collaboration on career development?

How could we measure the impact of international activities undertaken within the U.S., such as the availability of internationally trained teachers and faculty, international curricula, or international virtual learning projects on the development of global competence?

What added skills or experiences do you think that S&E researchers who work overseas would have that would be different than working in the US among foreign-born colleagues?

Do you think there is a difference between how researchers/educators would define global competence and how private industry would define it? If so, what are the differences?

How important is knowledge of the host-country language for: ability to function in the research setting; social interaction with peers; quality of the overseas experience? Is the language advantage/disadvantage more marked in some countries/regions than in others?

Section II: There are many types of international research projects available to STEM (Science, Technology, Engineering, and Mathematics) students - those that provide:

- Young researcher grants (e.g. international postdoctoral fellowship)
- International basic research award
- Applied research to meet a social need (e.g. engineers without borders)
• Industry-University training partnerships
• Virtual/cyber collaborations

Do these different programs have a different impact on the individual scientist or engineer in terms of global competence skills and career development? Are different criteria needed to evaluate each type of project?

The rising popularity of study abroad programs suggests a strong demand for an international experience among undergraduates. What impact can/do study abroad programs have on participation in international collaborations among graduate students?

Section III: Evaluating the Short and Long-Term impact of international experiences on individual scientists and engineers

Do educators/researchers who have participated in international collaborations come away with additional motivations to stay within their STEM fields? How would you measure this?

How would you go about developing sample comparison populations of students, educators, and researchers and STEM employees to empirically measure the long-term and short-term impacts of international education/research experiences?

What kind of testable hypotheses can clearly identify what abilities have been developed by those with foreign collaborations, including those who travel versus those who don’t travel?

How do we measure whether the career stage at which a person has the international experience – undergrad, graduate, post-doc, etc. - makes a difference in terms of impact?

What competencies do students gain from international research experiences that are valued by industry?

Does exposure to a foreign language make individuals more interested in doing research in a country where that language is used?

How can you measure the impact of conducting international research on such things as career development and staying in science or engineering?

What information would you, as a faculty member, need to convince your department head or dean that your international efforts are equal to or even more effective than those of colleagues who only work in the U.S.? In this case, think about faculty and career development, promotions, tenure, etc.

Are there measures other than grants, patents, and publications that capture the value of international work?
#2 Breakout Sessions: Evaluation at the Institutional Level

These breakout sessions will focus on measuring how education and research institutions are becoming more international in science and engineering.

**BACKGROUND**

Increased international engagement within institutions can include:
- Establishing formal ties with foreign institutions
- Establishing joint degree programs or curricula with foreign institutions
- Providing language/culture training specifically for STEM students
- Building international communities on campus
- Linking study abroad with research opportunities
- Having overseas campuses or providing faculty to foreign campuses
- Developing intellectual property agreements with foreign institutions
- Establishing offices and policies that foster international S&E activities at all levels
- Leveraging resources to facilitate international linkages
- Recruiting foreign students and faculty
- Establishing international partnerships with industry and other non-academic entities
- Serving as the center for a research and education network involving many US and foreign institutions

Are there other ways an institution can change to more effectively participate in the global S&E arena?

What are key factors (e.g., leadership at the highest level) for establishing and sustaining international programs?

What can institutions do to make it easier to undertake international activities (e.g., incentives, administrative, logistical, or financial assistance)?

Would it be useful/feasible to design and offer foreign-language courses aimed at STEM students? What curriculum changes in STEM degree requirements would be needed to accommodate foreign language study?

**EVALUATION**

How do we measure the impact of NSF funding on these various institutional characteristics?

Do programs have different impacts across different types of institutions (e.g., community colleges, small liberal arts colleges, land-grant institutions, research-focused institutions)?

What is the right time scale for measuring impacts of international activities on an institution?

How do we measure the interaction among and/or integration of these various international activities?
How could you measure whether NSF-funded activities have an impact on an institution beyond those directly involved in international travel?

How can NSF work with institutions to track and evaluate the impact of international experiences on its personnel over time?

How do we measure the impacts of industrial partners in NSF-funded international activities?

#3 Breakout Sessions: Evaluation at the Science and Engineering Knowledge Level

These sessions will focus on how to evaluate the impact of access to international collaborations on advancing science and engineering knowledge.

What added value do individuals bring to the classroom or laboratory because of their international experience? How can that be measured?

How can evaluation criteria be developed to measure the value added or impact in terms of quality of research and the educational components on other than an individual level?

Is it useful to compare the numbers and quality of new discoveries, methods, techniques, expertise, and instrumentation between projects that do and do not include international collaboration?

Does the rationale for international collaboration (e.g. access to experts, data, equipment, phenomena) differentially impact the added value of the international component of the research?

How do we measure the impact of where international collaborators go to conduct their research? (e.g. differences in language, culture, standard of living)

How can international collaboration change how science is being done? Is generation, communication, and integration of knowledge harder or easier? And how do we measure this?

How do we measure the effects of cyber communication on international collaboration? Does it increase or reduce travel? Does it enhance or detract from communication? Does it homogenize or catalyze cultural differences in how science and engineering is done?
#4: Joint Session: Integration—Next Steps

This joint session will focus on overall evaluation themes and the integration of the 3 elements (individual, institutional, science and engineering knowledge)

What can U. S. funding and funded institutions include in their infrastructure and policies to provide the flexibility needed to quickly respond to cutting-edge or new developments outside of the United States?

How can funding agencies and universities work more closely on a programmatic level with industry to integrate workforce skills needed for global competitiveness into science and engineering curricula?

Beyond focusing on individual, institutional, and knowledge elements are there other ways of evaluating international programs?

Is a research agenda needed to establish how learning takes place and how science and engineering is conducted in the international context?

How do we assess the complexity of each experience given different countries and regions and social and economic development?

What do other institutions like industry, private foundations, or other government agencies do to evaluate their international programs?

From your knowledge, are there other countries or international bodies doing program evaluations that we may tap into? Are there resources, groups, or tools that we can use in our own evaluation efforts?

How can we measure the impacts for the U.S. on the international contributions and participation?

How do we determine the right mix of programs to assure an adequate science and engineering workforce of the future? (undergraduate, postdoctorate, institutional partnerships)

Should we be concerned with measuring the impacts of NSF activities on other countries? If so how should we measure these activities? How can we measure the impact of foreign participation and funding on U.S. individuals, institutions, and science?

What is the right timeframe to measure the impact of international programs following their initiation given the increasing complexity, scope, and pace of international science?

What should NSF be doing to continuously monitor and improve international programs?

How can we enable PIs in universities to better evaluate their international activities?
